G E O S H A R E

Intercomparison of multiple global gridded crop models (GGCMs) within the framework of the Agricultural Model Intercomparison and Improvement Project and the Inter-Sectoral Impacts Model Intercomparison Project.

- Output for
 - 5 Crop Models
 - 5 Global General Circulation Models
 - 5 Representative Concentration Pathways
 - CO2 Fertilization and irrigation
 - 12 Crops
 - All the combinations ran from 1971 to 2099
- + 35,000 0.5°x0.5° grids with crop yields

The Problem

- Economic modelers use data aggregated to the country level
- NetCDF and other spatial data delivery formats are foreign to non-specialists
- Download of large grids is challenging even with good bandwith
- Storage is challenging for otherwise very good PCs
- How to make the data available to Users

The Solution

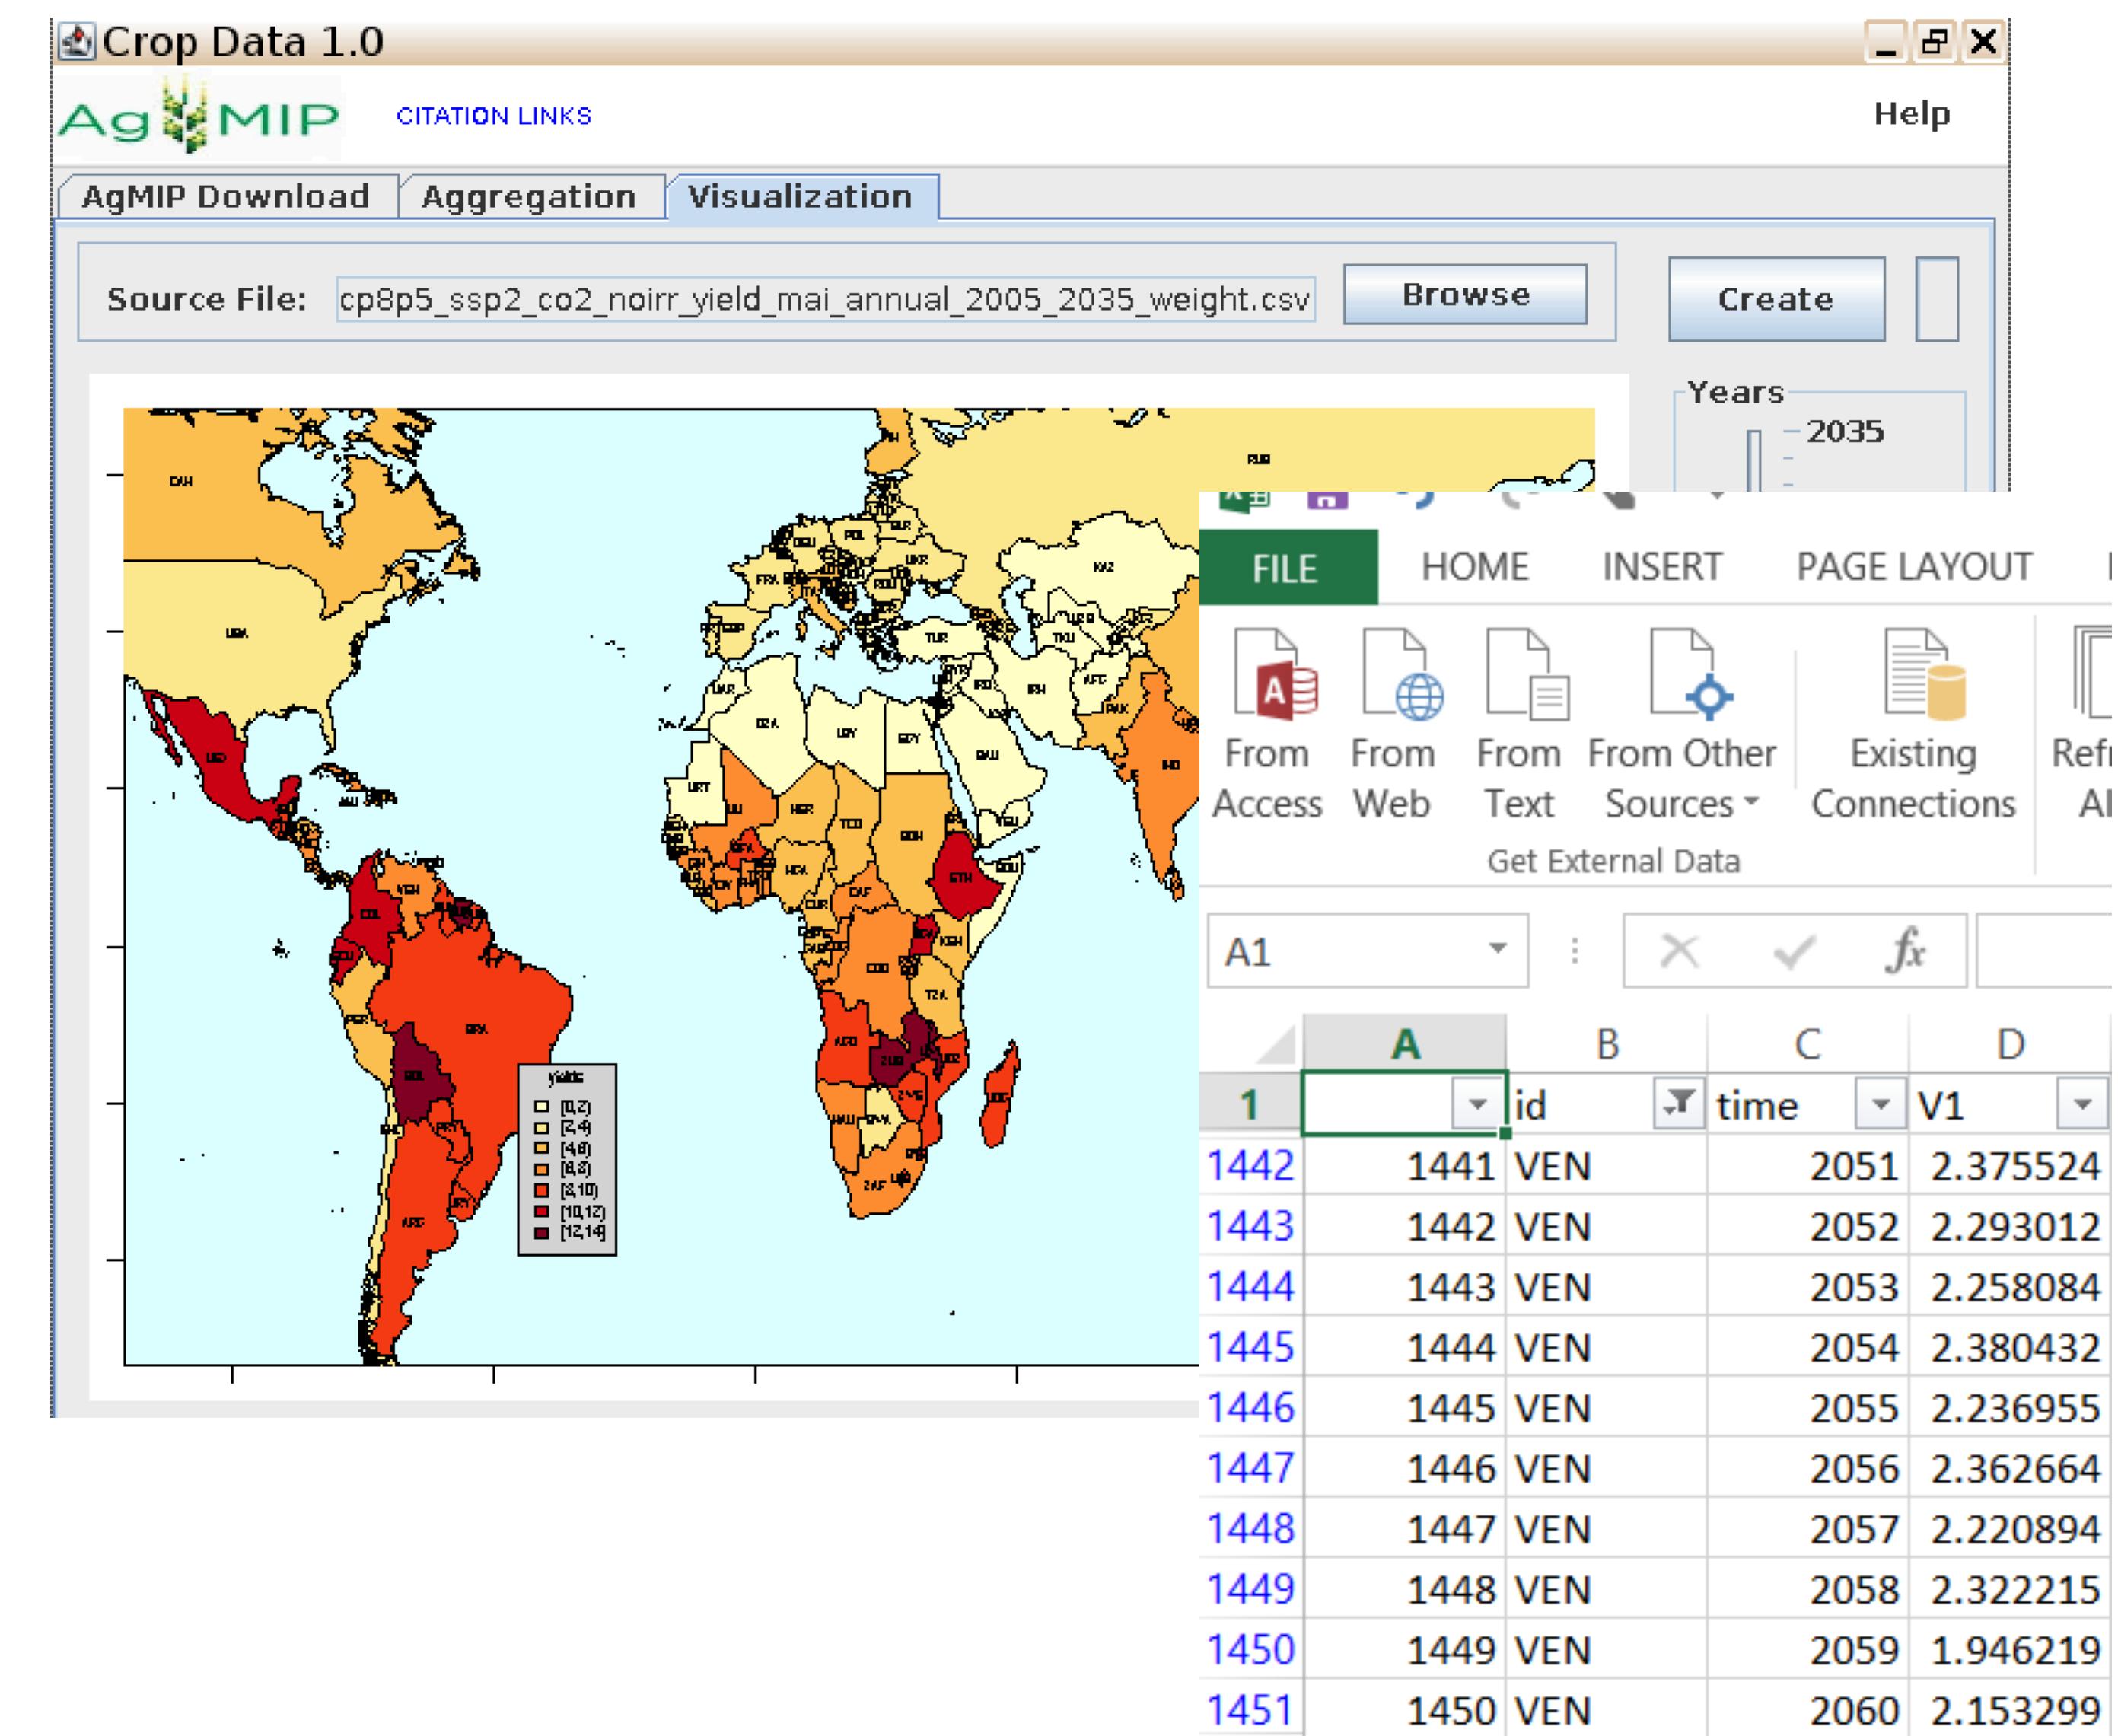

- Good all-around R Code:

- Reads data from Globus Online to the HUB
 
PLATFORM FOR SCIENTIFIC COLLABORATION
- Use aggregate() function
- Aggregates using mapping from XY coordinate to country, AEZs, up to the user.
- Calculate summary statistics (mean, etc.) or weighted averages using user provided weights (production, area, population, etc.)
- Wrap the R function around a Graphical User interface
